Optimization algorithms

LATEST SUBMISSION GRADE 100% 1. Which notation would you use to denote the 3rd layer's activations when the input is the 7th example from the 8th minibatch? (a) 3 (8)(7) a 3 {7}(8)) a [8]{7}(3) a [8]{3}(7) / Correct 2. Which of these statements about mini-batch gradient descent do you agree with? You should implement mini-batch gradient descent without an explicit for-loop over different minibatches, so that the algorithm processes all mini-batches at the same time (vectorization). Training one epoch (one pass through the training set) using mini-batch gradient descent is faster than training one epoch using batch gradient descent. One iteration of mini-batch gradient descent (computing on a single mini-batch) is faster than one iteration of batch gradient descent. / Correct 3. Why is the best mini-batch size usually not 1 and not m, but instead something in-between? If the mini-batch size is 1, you lose the benefits of vectorization across examples in the mini-batch. / Correct If the mini-batch size is m, you end up with stochastic gradient descent, which is usually slower than mini-batch gradient descent. If the mini-batch size is m, you end up with batch gradient descent, which has to process the whole training set before making progress. / Correct

If the mini-batch size is 1, you end up having to process the entire training set before making any

progress.

 Suppose your learning algorithm's cost J, plotted as a function of the number of iterations, looks like this:

Which of the following do you agree with?

- If you're using mini-batch gradient descent, something is wrong. But if you're using batch gradient descent, this looks acceptable.
- Whether you're using batch gradient descent or mini-batch gradient descent, something is wrong.
- If you're using mini-batch gradient descent, this looks acceptable. But if you're using batch gradient descent, something is wrong.
- Whether you're using batch gradient descent or mini-batch gradient descent, this looks acceptable.

✓ Correct

5. Suppose the temperature in Casablanca over the first three days of January are the same:

Jan 1st: $\theta_1 = 10^{\circ}C$

Jan 2nd: $\theta_0 10^{\circ} C$

(We used Fahrenheit in lecture, so will use Celsius here in honor of the metric world.)

Say you use an exponentially weighted average with $\beta=0.5$ to track the temperature: $v_0=0$, $v_t=\beta v_{t-1}+(1-\beta)\theta_t$. If v_2 is the value computed after day 2 without bias correction, and $v_2^{corrected}$ is the value you compute with bias correction. What are these values? (You might be able to do this without a calculator, but you don't actually need one. Remember what is bias correction doing.)

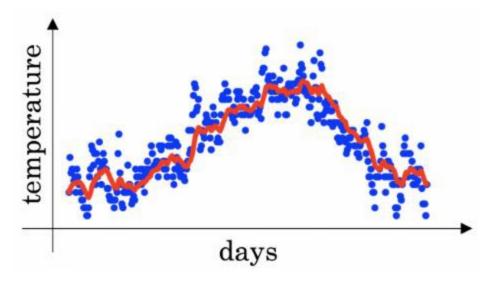

$$v_2 = 10$$
, $v_2^{corrected} = 7.5$

$$v_2 = 7.5, v_2^{corrected} = 7.5$$

$$v_2 = 7.5, v_2^{corrected} = 10$$

$$v_2 = 10, v_2^{corrected} = 10$$

- 6. Which of these is NOT a good learning rate decay scheme? Here, t is the epoch number.
 - $\alpha = \frac{1}{1+2*l}\alpha_0$
 - $\alpha = \frac{1}{\sqrt{t}}\alpha_0$
 - $\alpha = 0.95^{\dagger} \alpha_0$
 - $\bigcirc \alpha = e^t \alpha_0$
 - ✓ Correct
- 7. You use an exponentially weighted average on the London temperature dataset. You use the following to track the temperature: $v_t = \beta v_{t-1} + (1-\beta)\theta_t$. The red line below was computed using $\beta = 0.9$. What would happen to your red curve as you vary β ? (Check the two that apply)

- $\hfill \square$ Decreasing β will shift the red line slightly to the right.
- - ✓ Correct

True, remember that the red line corresponds to $\beta=0.9$. In lecture we had a green line \$\$\beta=0.98\) that is slightly shifted to the right.

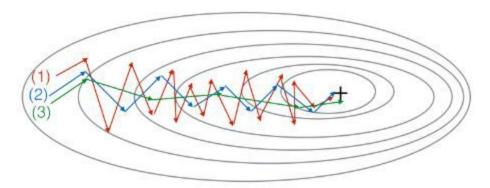

igspace Decreasing eta will create more oscillation within the red line.

. /	Correct

True, remember that the red line corresponds to $\beta=0.9$. In lecture we had a yellow line SS\beta = 0.98 that had a lot of oscillations.

Increasing β will create more oscillations within the red line.

8. Consider this figure:

These plots were generated with gradient descent; with gradient descent with momentum (β = 0.5) and gradient descent with momentum (β = 0.9). Which curve corresponds to which algorithm?

- (a) is gradient descent. (2) is gradient descent with momentum (small β). (3) is gradient descent with momentum (large β)
- (1) is gradient descent with momentum (small β). (2) is gradient descent. (3) is gradient descent with momentum (large β)
- (1) is gradient descent. (2) is gradient descent with momentum (large β). (3) is gradient descent with momentum (small β)
- (1) is gradient descent with momentum (small β), (2) is gradient descent with momentum (small β), (3) is gradient descent

✓ Correct

9. Suppose batch gradient descent in a deep network is taking excessively long to find a value of the parameters that achieves a small value for the cost function $\mathcal{J}(W^{[1]},b^{[1]},\ldots,W^{[L]},b^{[L]})$. Which of the following techniques could help find parameter values that attain a small value for \mathcal{J} ? (Check all that apply)

Try using Adam

✓ Correct

- Try initializing all the weights to zero
- Try mini-batch gradient descent

~	Correct
✓ Tŋ	tuning the learning rate $lpha$
~	Correct
V Tŋ	better random initialization for the weights
~	Correct
Which	of the following statements about Adam is False?
	usually use "default" values for the hyperparameters eta_1,eta_2 and ϵ in Adam ($eta_1=0.9$, $=0.999$, $\epsilon=10^{-8}$)
) Ad	am combines the advantages of RMSProp and momentum
Ad	am should be used with batch gradient computations, not with mini-batches.
	e learning rate hyperparameter $lpha$ in Adam usually needs to be tuned.
